

Mariana snailfish (*Pseudoliparis swirei*)

New heterotrophic flower: *Sciaphila sugimotoi*

# BIO1130 Introduction to the Biology of Organisms

**Prof: François Chapleau**

**Coordinator of laboratories:  
Dr Fabien Avaron**

Tapanuli orangutan  
(*Pongo tapanuliensis*)

**Coordinator of the course:  
Marc Charette**

**September 2019**

<http://earthsky.org/earth/top-10-new-species-2018>

New Shrimp: *Epimeria quasimodo*

Lab manual website : [biolab1.uottawa.ca](http://biolab1.uottawa.ca)

Science building third floor

Get a combination lock

No need for goggles

These species are newly discovered

Tapanuli

- Lives in small territory

- Threatening environment

Snailfish

- Lives deep in the ocean

- Considered top predator in his habitat

Flower

- No green- it doesn't do photosynthesis

- Feeds on organic material - feeds on fungus

Shrimp

# Science and skepticism

<http://blogs.discovermagazine.com/crux/2019/08/06/meet-homo-naledi-the-mysterious-human-cousin/#.XVrcy-NKjUk>

*Homo naledi* discovered in 2013 (study published in 2015): Height: 150 cm; weight: 45 kg; cranial volume: 465 cm<sup>3</sup> to 550 cm<sup>3</sup> (one third of *Homo sapiens*' volume)

Fossils: 1680+ bones belonging to 18 individuals.  
Found in two caves in South Africa

*Homo naledi*: In 2015, labeled as possible first species of genus *Homo* (nearly up to 2,400,000 years old).  
In 2017, viewed as a recent *Homo* species (probably less than 300,000 years).

Uncertainty is associated with science.

Always find new ways to express the answers

There is no truth in science

Open for test and justification

It is seen as a defect. The weak point is science gets close to the truth but never certain

Skepticism is important - why science progresses

2015 - new species of homo - was the oldest of the genes

For many it was the beginning of the research

*Homo naledi*

Issues-

The caves are difficult to access -

First human species

They took care of their dead - all of them found in the same place - funeral rights started 6000 years ago the bones were 2 million years old

Bones were 300 thousand years old not 2 million  
Q: Why were the bones there?

Point: Science doesn't stop with a discovery

## Mum's a Neanderthal, Dad's a Denisovan: First discovery of an ancient-human hybrid

Genetic analysis uncovers a direct descendant of two different groups of early humans.

### Cave girl's mum and dad were from different ancient human species

sky news

DNA analysis of bone fragments show she had one set of chromosomes from two different hominins.

07:19, UK  
Thursday 23 August 2018

---

Université d'Ottawa / University of Ottawa      Organismal biology      4      13:11

Last year, discovered female hominin result of crossbreed - male Denisovan - group of Asian species. They were two different species - found that species crossbreed

Fossil of a girl 90 thousand years old

Instead of a line of evolution it's a tree- large diagram of species

Question - are we dealing with one species or many species of humans?

# My other interests

**My first marathon  
Montreal 2007**

**Sea Kayak in  
Greenland**

**Cross-country skiing:  
Charlevoix crossing**

## Research profile

- Phylogenetics and systematics of flatfishes (sole, turbot, halibut, plaice)

Mayor of New York City (M. LaGuardia) posing in front of a 150 kilos halibut. Photo taken in 1939.

# Flatfish

Migration of the eye during the development of a flatfish

Symmetric fish

Fossil *Amphistium*

Flatfish

They have a blind side and eyes on one side  
Larva has eyes on both side and the eye migrate to the other side  
They lie on their blind side

My Q: As in every other evolution, what is the benefit of having both eyes on one side? How did this evolution occur?

Q: What is the advantage of eye migration?  
Darwin struggled to answer this evolution  
Key is to find an intermediate bw symmetric fish and flatfish

Fossil *Amphistium* is the intermediate between the two evolution

# Research profile: Flatfish

Flatfishes, chameleons of the sea

*Bothus mancus*

Some of them can adapt-change colours- to the environment

Q: What's happening in the cell to change pigments?

## Research profile: Flatfish

Eyed side

Blind side

# How to succeed in BIO1130

- **Attend lectures (really important)**
- **Download PPT (or PDF) presentations from Brightspace before lecture**
- **Fill empty spaces in PPT (or PDF) presentations during classes.**
- **Take supplementary notes on Powerpoint (or PDF) slides.**
- **After the lecture (same day or day after) : review your notes and ensure that you understand all concepts and examples**
  - **Study tools:**
    - **Textbook (Mastering Biology); Podcast (audio only)**
    - **Discussion groups (topics + Q&A)**
    - **Prof (email or office visit)**
  
- **Weekends : take a couple of hours to revise and ensure that you understand the course content from the beginning of lectures.**

Focus on concepts not details

An example of evolution:  
locomotion in Cheetahs

60 km/h (spike  
at 90km)

Thomson's gazelle

90 km/h

Grant's gazelle

Fastest mammal

Preys are also fast -

Running preys increased their speed by survival evolution

Cheetahs can do 0-70 in 2 seconds (element of surprise) - hunt takes less time than other hunts

Focus on Morphology

Scapula attached to the muscle but not to the vertebral column

Q: Why don't they have the flexibility we have if scapula is not directly attached to the vertebral column? Wouldn't this make them more flexible?

Q: Compare human scapula anatomy vs. Cheetah

Q: What's the advantage of having scapula in line with the legs?

## An example of evolution: the cheetah

### Mammals

- Pelvic girdle (pelvis) \_\_\_\_\_ to the vertebral column (propulsion)
- Pectoral girdle (scapula) \_\_\_\_\_ to the vertebral column (slides on the rib cage) (propulsion, orientation, stride length)

words: fused – not directly attached

### Hindlegs (Back)

Pelvis (hip) fused to vertebral column - this is what gives them speed

Unique to most of the mammals

Motor of the cheetah -pushing the animal forward

### Forelegs(Front)

Bone seems to slighting on the ribcage

They don't have the flexibility we have

Limbs attached to Scapula(human have it back of the rip cage)

Muscle allows the rib cage to stay stable - Head is allowed to stay stable so the animal can concentrate on the prey

Scapula is in line with the leg (limbs)

Rib cage is sitting **and its stretching** when the animal runs and keeps the head stable

If everything would be fused the head would go up and down

Legs are longer- longer strike

To prevent too much movement internal organs  
Cheetahs can run for a short amount of time  
Behavioural evolutionary - will never defend their prey - never fights for the prey - they wont want to get injured - important for reproductivity - eats their prey really fast - group eating their prey one of them watches for danger (another adaptation)  
Due to high success rate they leave the prey when needed

### An example of evolution: the cheetah

Appearance of limbs: 440 Myr

Q: where does this evolution come from?

Answer lies in Evolution of ancestor

Q: Where do legs come from?

Hindlimbs of mammals or any vertebrate comes from the fin of the fishes (for orientation)

Their hips attached to vertebral column - fish do not have a support structure once they invaded land they needed to support their body

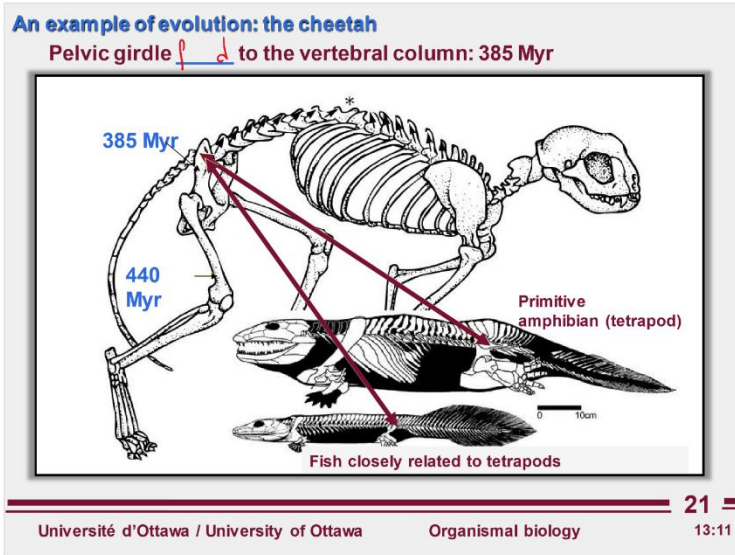

Morphology is similar to gazelle

First step of the process of evolution

Fish don't need body support cause environment supports it

Fins became support structure

Oldest fossil is 440 myr for the limbs

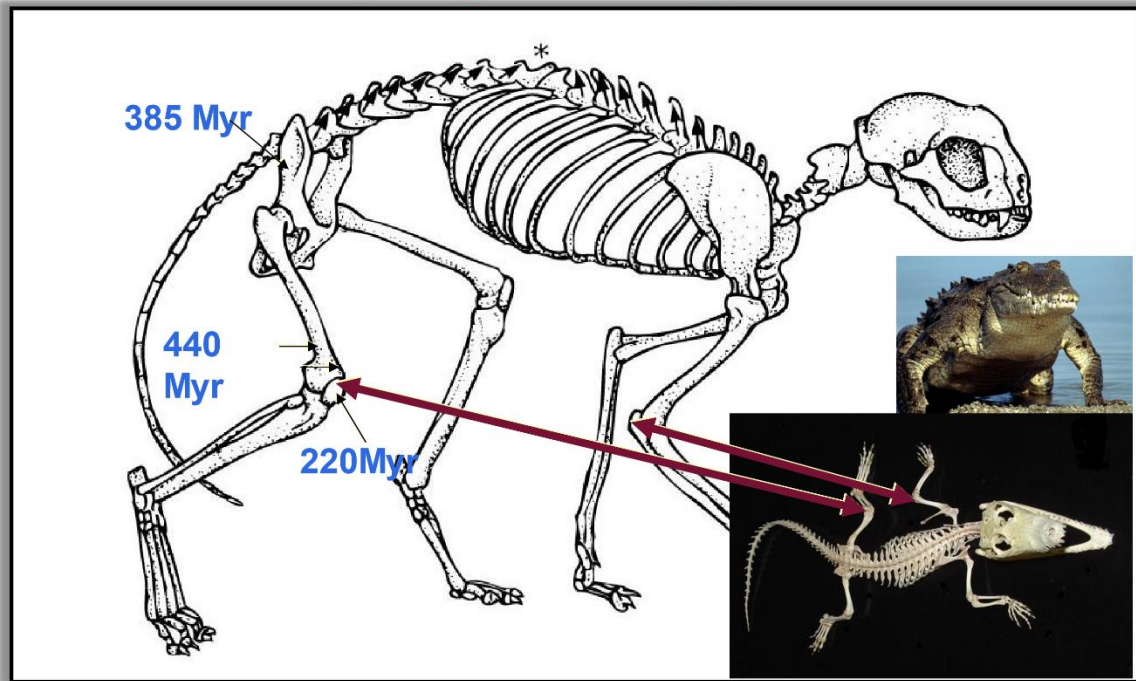

Hips attached to vertebral column feature evolved in tetrapods-  
one of the first things evolved with land invasion  
Provides support prevents squishing of internal organs allows  
vertebral column to be above the ground  
Oldest fossil is 385 yrs old

Word: fused

## An example of evolution: the cheetah

\_\_\_\_\_ of the knee and the elbow under the body  
(erect posture: 220Myr)

Supral posture - elbow away from the body, make torsions of the torso in order to move forward

Erect posture - elbow under the body, knees under the body - this shows some part of evolution there was a rotation of the elbow and the knee

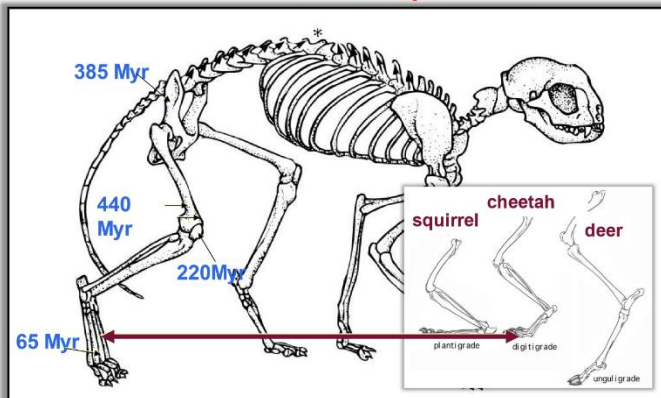

Oldest fossil that shows this 220 myr

Dinosaurs never had the rotation up the body elbows but had it under the body knees - they got large mainly because the rotation of the knee - they have kinda supral posture

Birds are modified dinosaurs - interior limbs became wings

**An example of evolution: the cheetah**

**Most carnivores walk on their fingers (d: 'i: g de) (65 Myr)**

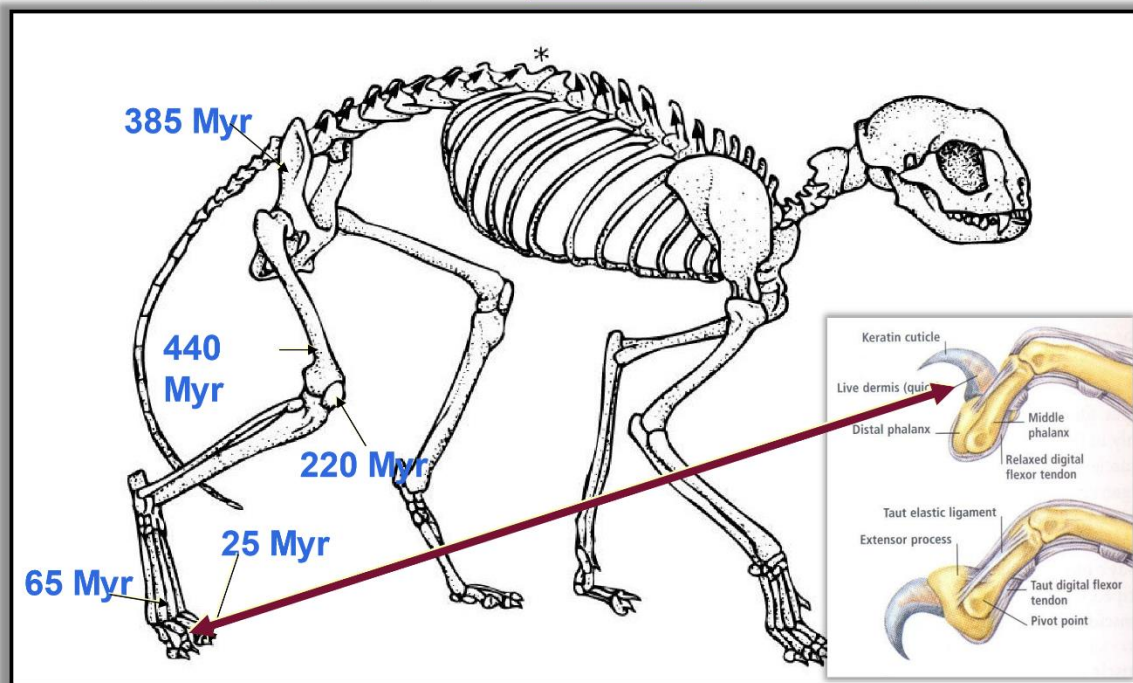

Carnivores walking tip of their digits  
 Advantage - sole of the foot becomes part of the land of the limb - means longer strike - more speed  
 Carnivores - claws is the important feature to catch their preys  
 Ghazel - increase in length of the limb - walk on their toes to increase speed (unguligrade) - no need to catch prey -- it makes it light  
 A lot of fusion of bones in the wrist - fused bones no muscles or ligaments  
 There is a lot of bone fusion in their toes and the limb that makes it faster - more movement not attached to the muscle - makes it light tip of the limb

Word: digitigrade

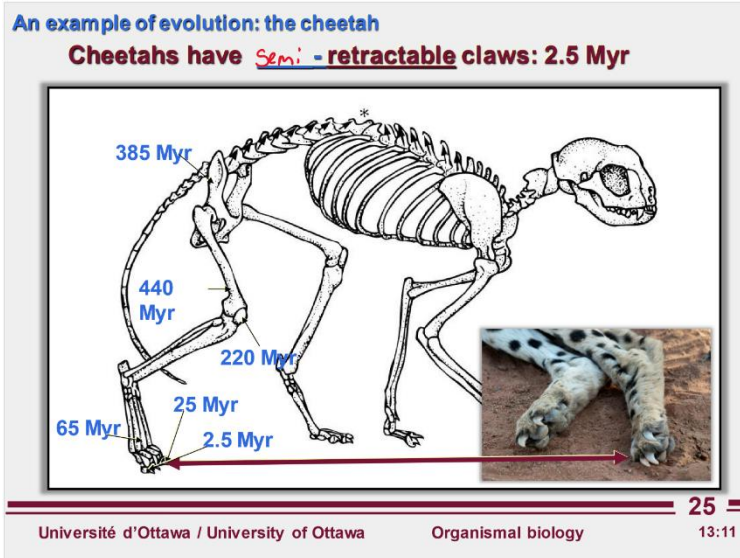

**An example of evolution: the cheetah**

**All cats (lion, tiger, cat,...) have \_\_\_\_\_ claws : 25 Myr**

Word: retractable  
 All cats have that

Advantage - keeping the claws inside protects the claw  
Oldest fossil 25 myr

Unique to cheetah  
Advantage - might be associated with speed  
Others don't because they have different types of hunting style - ex lion

An example of evolution: the cheetah

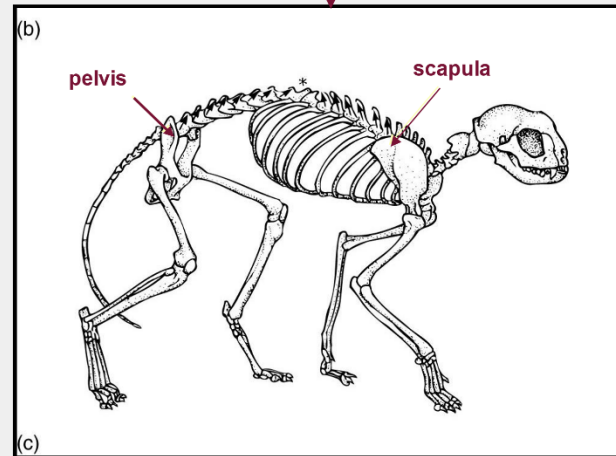

The hindlegs of a cheetah is the result of 440 Myr years of evolution.

## An example of evolution: the cheetah

- Adaptations of Vertebrates in cheetahs
  - locomotion organs (fins or limbs)
- Adaptations of terrestrial in cheetahs
  - Pectoral girdle (scapula) detached from the skull
  - Pelvic girdle (pelvis) fused to the vertebral column.
- Adaptations of in cheetahs
  - Rotation of the knees and elbows under the body (support and/or speed)
- Adaptations of the order in the Cheetahs.
  - Walk on fingertips (digitigrade)

27

Words: tetrapods, mammals, carnivores

Presence of limbs good characteristics of vertebrates

Tetrapods - 4 legged animal

Front limb attached to cranium - one thing evolution - detached from the cranium - allowed the evolution of the neck - unique to tetrapods

## An example of evolution: the cheetah

### Adaptations of the cheetah compared to other felines

- Fur pigmentation
- Long and thin limbs especially in the distal end ( )
- lightweight, slender and muscular body ( )
- Flexibility of the spine (speed, stride length)
- Wide nostrils, heart and lungs with high functional capacity

Words: cheetah, stride length, speed

Spotted fur allows it (in savannah) to get close to the prey - surprise effect

Among the most flexible spines of all the cats - 1 jump - 7meter - due to the extension of vertebral column

These are unique to cheetah

## Thus, what is a cheetah?

- A cheetah is a mammal characterized by few derived traits (evolutionary innovations) that distinguishes it from other feline species.
  - The species is the result of 3,500 Myr of evolution. Why?
  - More than 99% of its characteristics have evolved in species that are now extinct.
  - Less than 1 % of its features are unique.
- So the cheetah is more the result of the \_\_\_\_\_ than of its own history.
- This applies to all living species, including \_\_\_\_\_.

Words: history of its ancestors, humans

Because its presence is linked with its ancestor - common ancestor linked with first living being has in common? DNA

DNA is the characteristic that unites all the species

Notion of articular speech - associated with only humans

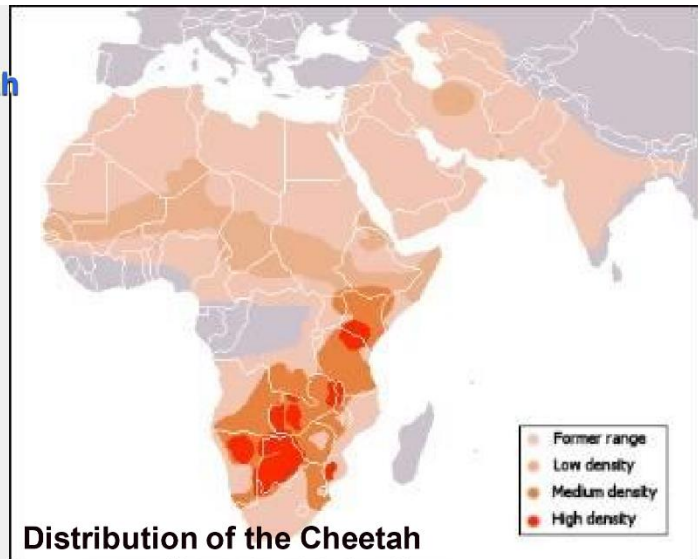

Point - only few features differentiate humans others are the same

## An example of evolution: the cheetah

### □ Importance of genetic variability

Royal cheetah  
(species or \_\_\_\_\_?)

Word: mutation

Diversity of cheetah - different pigmentation on their fur

Answer came in a zoo when one of the kittens were royal cheetah

Royal cheetah is not a specie it's mutated

Changes the development of pigmentation

Cheetah DNA - almost clones of one another

You can take a skin and make a skin graph and the skin will take

Why? What's the impact?

Population might go through population bottleneck probably the diversity of cheetahs that we have now survived

Genetic variability is low (important for conservation biology later on in the course)

Problem with this - Very little resiliency - disease that kills 1 will ill them a similarity

**An example of evolution:  
the cheetah**

- ‘cheetah’  
(extinct for 20,000 years)
- Pronghorn  
(North America)

***Miracinonyx: ‘American cheetah’  
chasing a pronghorn***

---

Université d’Ottawa / University of Ottawa      Organismal biology      31      13:11

Word: American

99% of the species are now extinct - massive extinction of human impact

Coevolution - as prey gets faster predator gets faster.

Pronghorns are have high speed but their predator can run only up to 60 km/h

Extinction of the American cheetah is unknown (fossil are important in or

what's going in the current phana (fanah))

North American cheetah is more similar to a puma than African cheetah (n of convergent evolution- species has evolved similar speed independently come from different species

## Science and religion

(Discussion group will be activated during the first week of class)

- **To the following question from a Globe and Mail reporter (March 17 2009) « Do you believe in evolution? », the Canadian Minister of science and technology at that time answered : “ I'm not going to answer that question. I am a Christian, and I don't think anybody asking a question about my religion is appropriate.”**
  - As a student in a science course, what do you think of the minister's answer?
  - Can faith (religion) be part of a methodological process to answer scientific questions? If no, why? If yes, how?
  - Can faith (religion) provide us with objective knowledge about the origin of life? Or about the origin of our species? If no, why? If yes, how?

Give your answer or your opinion (anonymously or not) in the *discussion group* dealing with this issue on Virtual Campus ( Brightspace). Remember that you will be anonymous to your colleagues but not to the instructors of the course. Please be constructive and courteous in your comments or they will be deleted.
